FarmLens

The three-minute walkthrough

Home → Land → Weather → Crops → Finn → Scenarios. Keep Dubbo prepared; timings include clicks.

0:00–0:25 · The question

On screen: Home, then Explore your land.

Meet FarmLens, a friendly farming companion built around one question: what could I grow on this land? Climate, soil and crop information often live in different places. FarmLens brings them into one view, with reasons you can inspect. Let me show you the local prototype.

0:25–0:55 · Start with the land

On screen: Dubbo → Land snapshot → View land, then close the image.

I'll start with Dubbo. You can also choose a point on the NSW map. The snapshot combines modelled Australian soil with mapped land cover. The image gives geographical context around the pin. Its survey date is visible: this Dubbo block dates to 2009, so it is not a live view. The preset is a town-centre demo point, not a verified farm.

0:55–1:15 · Weather in context

On screen: Seven-day weather; point to the collapsed Seasonal climate summary.

Here is the seven-day weather outlook. The crop screen uses longer-term climate patterns, kept separately. The app shows dates and source status, including when data are cached. That distinction matters: a forecast, a historical average and a soil model are different kinds of evidence.

1:15–1:50 · Crop options and their reasons

On screen: Scroll to Crop options; open Canola, inspect factors, close.

Now we can explore crop candidates. Each score uses explicit ranges and weights for climate and soil factors. NSW guidance adds checks and constraints, while the weakest factor is visible. Opening a crop shows the detail, including what has not been assessed. A high score is a stronger environmental screen, not a probability of success. The next step is still local advice and field measurements.

1:50–2:25 · Meet Finn

On screen: Return to the report header → Ask FarmLens → Why this crop?

Finn makes that report easier to discuss. I can ask why a crop appears, what to watch, or how to explore water and budgets. For this demo, Finn uses supported questions and the existing report numbers. Typed questions stay in the browser. Optional model-written crop explanations are separate and receive only the approved numeric inputs.

2:25–3:00 · Trade-offs and next step

On screen: What about water? → Open water planner; briefly indicate Crop budget.

The water pilot explores ten historical seasons under assumptions you can change. The budget tool explores gross margin from entered yield, price and costs. Both sit alongside the shortlist; neither predicts the farm's future return. What I want to test next is whether this makes a useful first conversation with a farmer or agronomist. Indicative only. Check with a local agronomist.

FarmLens

The 60-second backup

Meet FarmLens, a local prototype for exploring what could grow on land in NSW. Drop a pin to bring climate, modelled Australian soil and crop requirements into one report. The land snapshot includes dated imagery, while the crop shortlist explains its scores and limitations. Finn is a friendly guide to that report, answering supported questions locally. Separate water and budget tools let you explore assumptions. The purpose is a clearer starting point for local advice, not a yield or profit forecast. I'm looking for feedback on what would make it useful in practice. Indicative only. Check with a local agronomist.

Before you present

1. Start the local server and open Home at 127.0.0.1:8503.
2. Prepare Dubbo using cached data. Confirm the forecast dates and imagery status; browser map tiles and imagery may still need internet.
3. Open Finn once. Use the recorded screenshots if a request takes more than five seconds, and call them recorded examples.
4. Keep the default water/budget tools as demonstrations of assumptions. Do not describe archived prices as current returns.

If someone asks about reliability

- Soil values are modelled; the imagery is dated context.
- Scores are provisional indices, not success probabilities or yield forecasts.
- Finn is a bounded local report guide. Optional OpenAI crop wording is separate.
- 305 Python and 43 JavaScript tests passed. Those checks establish software behavior, not agronomic accuracy.

> **Indicative only. Check with a local agronomist.**
> Next: agronomist review and comparison with field measurements.

Full script, recording cues, source credits and fallback images accompany this handout in showcase-demo-script.md and showcase-release-notes.md.
